

1 · The experiment — measure it!

Reaction Time (8 dots): my **average** _____ ms · fastest _____ ms

Run **MATB** three times: practice, then ① quiet and ② noise from the Condition Lab. After each run write the **Final Score** shown at the top of the "Simulation Complete" screen (tap **Skip** if asked for a name).

On a phone: Monitoring → tap F1/F2 or the gauge · Tracking → drag the cursor when it says MANUAL · Comms → tick the radio, tap – / + · Resource → tap pumps on/off.

Run	Final score
Practice (dry run)	
① Baseline (quiet)	
② Stressed (cabin noise)	

My change: the noise made my score ↓ **down** / ↑ **up** by about _____ %.

Learning effect: like a new sport — you improve, then plateau. Sleep & mood still matter.

Why did the noise change performance?

2 · Design your module (Blueprint Designer)

- ☐ Kept at least 1 life-support unit
- ☐ Added at least 2 stowage units
- ☐ Added sleeping quarters
- ☐ Every module has a clear path to the entrance
- ☐ Mission Success ≥ 70 → **My score:** _____ · **Simulated reaction time:** _____ ms

3 · Sketch your blueprint

Label at least **3** features that protect the crew's mind (Acoustic zone, Plant wall, Virtual window, Sleeping quarters) and the **entrance + corridors**.

draw here...

Our pitch (2 sentences): "We added _____ to protect _____, and our Mission Success was _____."

Exit ticket — draft here, then copy each answer onto a sticky note (name on the note):

- ① One thing in the architectural environment that **helps** cognition: _____
- ② One thing that **hurts** it: _____
